Section 1: Recap

Hominids

'Hominids' (lat. *hominidae*) refer to all species after our LCA (last common ancestor) with orangutans, gorillas, and chimpanzees.

Table 1. *a. A taxonomy of the living higher primates that recognises the close genetic links between Pan and Homo*

Superfamily Hominoidea ('hominoids')
Family Hylobatidae
Genus <i>Hylobates</i>
Family Hominidae ('hominids')
Subfamily Ponginae
Genus <i>Pongo</i> ('pongines')
Subfamily Gorillinae
Genus <i>Gorilla</i> ('gorillines')
Subfamily Homininae ('hominines')
Tribe Panini
Genus <i>Pan</i> ('panins')
Tribe Hominini ('hominins')
Subtribe Australopithecina ('australopiths')
Genus <i>Ardipithecus</i>
Genus <i>Australopithecus</i>
Genus <i>Paranthropus</i>
Subtribe Hominina ('hominans')
Genus <i>Homo</i>

Wood & Richmond (2000), p. 21.

Taxonomic Considerations

How are species classified?

- ▶ **Morphometrics:** Analysing and comparing the morphological shape of fossils.
- ▶ Behavior: Analysing archaeological assemblages (mostly stone tools).
- ▶ Genetics: Analyses of different parts of the (available) DNA, applying phylogenetic methods from evolutionary biology.

Cranial Morphology

Typical features for distinction:

- ▶ **Globularity** (globular vs. flat)
- ▶ **Occipital torus** (rounded vs. angled)
- ▶ **Supraorbital torus** (robust vs. less pronounced)
- ▶ **Mandibular chin** (vertical vs. receding)
- ▶ **Facial angle** (orthognathic vs. prognathic)

Note: Some anatomical variation due to sexual dimorphism.

Cranial Capacity

DeSilva et al. (2021). When and why did human brains decrease in size?

DeSilva et al. (2023). Human brains have shrunk: the questions are *when* and *why*.

Conclusions by DeSilva et al. (2021).

- ▶ “We find that hominin brains experienced positive rate changes at 2.1 and 1.5 million years ago, coincident with the early evolution of *Homo* and *technological innovations* evident in the archeological record.”
- ▶ “[...] human brain size reduction was surprisingly recent, *occurring in the last 3,000 years*. Our dating does not support hypotheses concerning brain size reduction as a by-product of body size reduction, a result of a shift to an agricultural diet, or a consequence of self-domestication.”
- ▶ “[...] decrease in brain size may instead result from the *externalization of knowledge* and advantages of group-level decision-making due in part to the advent of social systems of distributed cognition and the storage and sharing of information.”

Section 1: Recap

Section 2: New Members of the Hominin Family

Section 3: Human Morphology

Section 4: Geometric Morphometrics

Exercise

For the following specimen crania, prepare a table with the *binary feature values* for the following features: *globularity*, *occipital torus*, *supraorbital torus*, *mandibular chin*, *facial angle*.

Does the *H. sapiens* cranium have more in common in terms of these feature values with the species in its *direct lineage* than with other hominin species?

Section 1: Recap

Section 2: New Members of the Hominin Family

Section 3: Human Morphology

Section 4: Geometric Morphometrics

Summary

References

Solution

Species	globularity	occ. tor.	supraorb. tor.	chin	face
Au. afar.	flat	angled	robust	NA	progn.
Au. afric.	globular	round	non-robust	NA	progn.
P. boisei	flat	angled	robust	NA	progn.
H. ergaster	flat	angled	robust	NA	progn.
H. neand.	flat	angled	robust	receding	progn.
H. sapiens	globular	round	non-robust	vertical	orthogn.

The *H. sapiens* cranium seems to have most features in common with the *Au. africanus*, which is not in its direct lineage (as far as the tree by Klein 2009 is concerned).

Dental Morphology

FIGURE 4.28. Facial and occipital views of *Pan troglodytes* (chimpanzee), *Australopithecus afarensis*, *A. africanus*, *Paranthropus robustus*, *P. boisei*, and *Homo habilis* (redrawn after White et al. [1981], figs. 9, 10). Note that *A. afarensis* and the chimpanzee share pronounced subnasal prognathism, relatively large anterior teeth, a diastema between the lateral incisor and the canine, confluence of the temporal and nuchal lines, great breadth of the cranial base, and other features. Note also that *A. afarensis* differs from other hominins in all these respects. AL = Hadar; STS = Sterkfontein; SK = Swartkrans; KNM-ER = Kenya National Museum East Rudolf.

Postcranial Morphology

Postcranial Morphology

In *H. sapiens* compared to earlier species of genus *Homo*, we typically find:

- ▶ **Long limbs**
- ▶ **Narrow thorax**
- ▶ **Narrow hips**
- ▶ **More gracile bones**

Note: We still find some variation across world populations due to *drift* and *adaptations*. Cranial and pelvic structure evolves mostly neutrally, while limbs (and likely the thorax) are more plastic and subject to adaptation.

Section 4: Geometric Morphometrics

Linear measurements vs. landmarks

Traditional morphometric analyses would use **linear measurements** (between predefined points) for univariate or multivariate analyses. More recently, these points themselves – i.e. the so-called **landmarks** – are considered as the 2D or 3D representation of the fossil (with scaling and normalizations).

Baab et al. (2012). The shape of human evolution: A geometric morphometrics perspective.

Figure 2. Example of two simple interpoint measurements, basion to bregma and inion to glabella. (Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.)

TABLE 1. Comparison of Measurement Data Derived from Linear and Coordinate Data

Type of data	Measurement	Data
Linear	basion - bregma	9.7
	inion - glabella	13.1
Coordinate (x, y)	basion	12, 2.4
	bregma	10, 11.3
	inion	16.5, 4.1
	glabella	3.8, 8.0

Fig. 3. (a) Plot of PC 1 vs. PC 2 and (b) PC 1 vs. PC 3 of neurocranium + face PCA. The cranial shape associated with the negative (left column) and positive (right column) ends of (c) PC 1, (d) PC 2, and (e) PC 3, in right lateral and anterior views. Wireframe refers to that illustrated in Fig. 1.

Baab & McNulty (2008). Size, shape, and asymmetry in fossil hominins: The status of the LB1 cranium based on 3D morphometric analyses.

Conclusions by Baab & McNulty(2008).

- ▶ “The cranial morphology of LB1 clearly aligns it with the **genus Homo**, even though LB1 is smaller in both body and brain size than any other members of our genus.”
- ▶ “[...] the cranial shape of LB1 largely fits a model for a small specimen of **archaic Homo**.”
- ▶ “[...] it is unnecessary to postulate additional factors, such as microcephaly, in the absence of strong evidence to support this claim.”

Baab & McNulty (2008). Size, shape, and asymmetry in fossil hominins: The status of the LB1 cranium based on 3D morphometric analyses.

Summary

Summary

- ▶ Some recently discovered hominin fossils include: *Homo naledi*, *Homo floresiensis*, *Homo luzonensis*. These illustrate that there were **sister lineages with unexpected features** (small brains, small stature, robust features) living alongside *Homo sapiens* in Africa and across the world until fairly recently (<100 Kya).
- ▶ The distinctive **morphological features** of hominin species include: **globularity**, shape of **occipital torus**, **brow ridges** (supraorbital torus), **chin**, and **facial angle**, the breadth of **thorax**, **body size**, and **cranial capacity**.
- ▶ Apart from qualitative assessments of these features, **geometric morphometrics** offers finer-grained statistical analyses.
