Q&A

Lecture 5

- ▶ *In the Gamut notation for arbitrary predicate constants (e.g. A and B) [slide 23], what is the rule for applying indices here?* – Looking at the Gamut examples again, I think that the indices can be dropped in this case (I've changed this in the slide). Only if we define a translation key for a given set of sentences do we need to use indices to disambiguate.
- ▶ *In the first example on slide 28, why is there an index for B but not for p and j ?* – Note that we have defined the translation key in the slide before. For p and j we do not need indices to disambiguate, since they only occur once for this set of sentences.
- ▶ *In the last example on slide 36, wouldn't it be better to use different variables (x and y) for being bound by different quantifiers (rather than just x)?* – This is a tricky one. Note that Gamut (1991), Volume 1, p. 77, explicitly allow formulas where the same variable is bound by different quantifiers. However, you are right that it is probably better to visually further disambiguate by using different variables.

The Vocabulary

Similar as for propositional logic, we can define a **language L for predicate logic**. In this case, the “vocabulary” of L consists of

- ▶ a (potentially infinite) supply of **constant symbols** (e.g. a, b, c , etc.),
- ▶ a (potentially infinite) supply of **variable symbols** representing the constants (e.g. x, y, z , etc.),
- ▶ a (potentially infinite) supply of **predicate symbols** (e.g. A, B, C , etc.),
- ▶ the **connectives** (e.g. $\neg, \wedge, \vee, \rightarrow$, etc.),
- ▶ the **quantifiers** \forall and \exists ,
- ▶ as well as the round brackets ‘(’ and ‘)’.
- ▶ (The equal sign ‘=’.)

Summary

References

English sentences:

- (1) Socrates admires someone.
- (2) Socrates is admired by someone.
- (3) All teachers are friendly.
- (4) Some teachers are friendly.
- (5) Some friendly people are teachers.
- (6) All teachers are unfriendly.
- (7) Some teachers are unfriendly.

Translations:

- (1) $\exists y A s y$
- (2) $\exists x A x s$
- (3) $\forall x (T x \rightarrow F x)$
- (4) $\exists x (T x \wedge F x)$
- (5) $\exists x (F x \wedge T x)$
- (6) $\forall x (T x \rightarrow \neg F x)$
- (7) $\exists x (T x \wedge \neg F x)$

Summary

References

Notes:

We have to add Tx : x is a teacher to the key.

Due to the so-called commutativity of \wedge , i.e. $\phi \wedge \psi \equiv \psi \wedge \phi$, we have that the predicate logic expressions in (4) and (5) are seen as equivalent too. However, the asymmetry might be seen as actually relevant in the natural language examples.

Generally, we have that $\forall x \neg \phi \equiv \neg \exists x \phi$.

The Syntax: Recursive Definition

Given the vocabulary of L we then define the following clauses to create formulas of L .

- (i) If A is an n -ary predicate letter in the vocabulary of L , and each of t_1, \dots, t_n is a constant or a variable in the vocabulary of L , then At_1, \dots, t_n is a formula in L .
- (ii) If ϕ is a formula in L , then $\neg\phi$ is too.
- (iii) If ϕ and ψ are formulas in L , then $(\phi \wedge \psi)$, $(\phi \vee \psi)$, $(\phi \rightarrow \psi)$, and $(\phi \leftrightarrow \psi)$ are too.
- (iv) If ϕ is a formula in L and x is a variable, then $\forall x\phi$ and $\exists x\phi$ are formulas in L .
- (v) Only that which can be generated by the clauses (i)-(iv) in a finite number of steps is a formula in L .

Definition: *Formula vs. Sentence*

There is a further distinction between **formulas** and **sentences** in predicate logic. Namely, sentences are a subset of formulas for which it holds that: “A sentence is a formula in L which **lacks free variables**.”¹

Gamut, L.T.F (1991). Volume 1, p. 77.

Sentence

Aa

$\forall x(Fx)$

$\forall x(Ax \rightarrow \exists yBy)$

Not a Sentence (but Formula)

Ax

Fx

$Ax \rightarrow \exists yBy$

Logic

Summary

References

¹Free variables, in turn, are precisely defined by Gamut (1991), p.77 in their Definition 3. We will simply state here that a variable is free if it is not within the scope of a quantifier.

Interpretation Functions

“The interpretation of the constants in L will therefore be an attribution of some entity in D to each of them, that is, a function with the set of constants in L as its domain and D as its range. Such functions are called **interpretation functions**.”

$$I(c) = e. \quad (1)$$

“ $I(c)$ is called the *interpretation of a constant c* , or its *reference* or its *denotation*, and if e is the entity in D such that $I(c) = e$, then c is said to be one of e ’s names (e may have several different names).”

Gamut, L.T.F (1991). Volume 1, p. 88.

Example

$$I = \{\langle m, e_1 \rangle, \langle s, e_1 \rangle, \langle v, e_1 \rangle\}$$

$$I(m) = e_1$$

$$I(s) = e_1$$

$$I(v) = e_1$$

Definition: A model \mathbf{M} for language L^2

“A model \mathbf{M} for a language L of predicate logic consists of a domain D (this being a nonempty set) and an interpretation function I which [...] conforms to the following requirements:

- (i) if c is a constant in L , then $I(c) \in D$;
- (ii) if B is an n -ary predicate letter in L , then $I(B) \subseteq D^n$.”

Gamut, L.T.F (1991). Volume 1, p. 91.

Example

$$D = \{e_1, e_2, e_3\}$$

$$I(m) = e_1$$

$$I(j) = e_2$$

$$I(p) = e_3$$

$$I(S) \subseteq D^2$$

Translation key: j : John; p : Peter; m : morning star; Sxy : x sees y .

²The approach we follow here is called *Approach A* or *the interpretation of quantifiers by substitution* in Gamut (1991), p. 89. There is also another alternative Approach B, which we do not consider here.

Definition: The valuation function V_M

“If \mathbf{M} is a model for L whose interpretation function I is a function of the constants in L onto the domain D , then V_M , the valuation V based on M , is defined as follows:”

- (i) If Aa_1, \dots, a_n is an atomic sentence in L , then $V_M(Aa_1, \dots, a_n) = 1$ if and only if $\langle I(a_1), \dots, I(a_n) \rangle \in I(A)$.
- (ii) $V_M(\neg\phi) = 1$ iff $V_M(\phi) = 0$.
- (iii) $V_M(\phi \wedge \psi) = 1$ iff $V_M(\phi) = 1$ and $V_M(\psi) = 1$.
- (iv) $V_M(\phi \vee \psi) = 1$ iff $V_M(\phi) = 1$ or $V_M(\psi) = 1$.
- (v) $V_M(\phi \rightarrow \psi) = 0$ iff $V_M(\phi) = 1$ and $V_M(\psi) = 0$.
- (vi) $V_M(\phi \leftrightarrow \psi) = 1$ iff $V_M(\phi) = V_M(\psi)$.

Valuation Example

Given a Model of the world \mathbf{M} , consisting of D and I , and some formula ϕ which adheres to predicate logic syntax (and which consists of atomic sentences and or quantifications with bound variables), we can then evaluate the truth of ϕ as follows.

Model \mathbf{M}

$$D = \{e_1, e_2, e_3\}$$

$$I = \{\langle j, e_1 \rangle, \langle p, e_2 \rangle, \langle m, e_3 \rangle, \langle S, \{\langle I(j), I(m) \rangle, \langle I(p), I(m) \rangle\} \rangle\}$$

Translation key: j: John; p: Peter; m: morning star; Sxy: x sees y.

Valuation

“John sees the morning star”: $V_M(Sjm) = 1$ (according to (i))

“Everybody sees the morning star”: $V_M(\forall x Sxm) = 0$ (according to (vii))³

³This valuation gives 0 since the morning star (m) is a constant c in L, but it does not see itself, i.e. $\langle I(m), I(m) \rangle \notin S$.

Section 2: Beyond Predicate Logic

Beyond Predicate Logic

We have seen that predicate logic is an extension of propositional logic, by introducing predicates and quantifiers. **Predicate logic** might itself be superseded by another logical system, called **second-order logic**.

Gamut, L.T.F (1991). Volume 1, p. 168.

Take the following English sentences:

- (1) Mars is red.
- (2) Red is a color.
- (3) Mars has a color.
- (4) John has at least one thing in common with Peter.

How can we translate these into logical expressions?

of Lecture 5

Section 2:
Beyond Predicate
Logic

Section 3: The
Vocabulary

Section 4: The
Syntax of
Second-Order
Logic

Section 5: The
Semantics of
Second-Order
Logic

Summary

References

The adjective “red” is a **property of individuals**. Hence, the first sentence can be straightforwardly translated into predicate logic notation as

(5) Rm (**Rx** : x is red, m : Mars)

What about the second sentence? We could stick with standard predicate notation and translate it into

(6) Cr (Cx : x is a color, **r** : red)

Note however, that now we have treated “red” once as a property of individuals in (5), and once as an individual itself in (6). In predicate logic terms it is once represented as a **predicate constant**, and once as a **constant**.

Second-Order Predicates

To circumvent this discrepancy, we can construe the predicate *x is a color* not as a property, but as a **property of properties**. \mathcal{C} then represents a so-called **second-order property**, i.e. a **second-order predicate** over the first-order predicate *x is red*.

Instead of

(7) $\mathcal{C}r$ ($\mathcal{C}x$: *x is a color*, r : *red*),

we then get

(8) $\mathcal{C}R$ ($\mathcal{C}X$: *X is a predicate with the property of being a color*, Rx : *x is red*)

Note: We introduce **two** new sets of symbols here compared to standard predicate logic, a) the set of *second-order predicates*, and b) the set of *first-order predicate variables*. See details below.

Summary

References

First-Order and Second-Order Logic

A **second-order logic** language L' is then an extension to a standard predicate logic language L by adding second-order predicates to L . The original language L is then sometimes referred to as **first-order logic** language.

Further Examples:

- (9) $\exists X(CX \wedge Xm)$ (English sentence: “Mars has a color.”)
- (10) $\exists X(Xj \wedge Xp)$ (English sentence: “John has at least one thing in common with Peter.”)
- (11) $\exists \mathcal{X}(\mathcal{X}R \wedge \mathcal{X}G)$ (English sentence: “Red has something (a property) in common with green.”)

Historical Side Note

It is disputed whether second-order predicates are necessarily needed in logical systems generally, and for natural language logic in particular. Some of the reasons for this include:

- ▶ There is **no completeness theorem** for second-order logic (see Gamut 1991, Volume 1, p. 171), while for first-order logic there is.
- ▶ W. V. Quine rejected the idea that **quantification over predicates** makes sense. He conceptualized predicates as an abbreviation for an incomplete sentence, e.g. F standing for “...is friendly”, and such *incomplete sentences* are not to be seen as *objects* to quantify over.

See also discussion on https://en.wikipedia.org/wiki/Second-order_logic under *History and disputed value*.

Section 3: The Vocabulary

Vocabulary (shared with First-Order Logic)

The vocabulary of a second-order logic language L consists of symbols which are *shared with first-order logic languages*, and some which need to be introduced especially to fit the *second-order properties*. The once **shared with first-order logic** languages are:

- ▶ A (potentially infinite) supply of constant symbols (e.g. a, b, c , etc.),
- ▶ a (potentially infinite) supply of variable symbols representing the constants (e.g. x, y, z , etc.),
- ▶ a (potentially infinite) supply of **first-order predicate constants** (e.g. A, B, C , etc.),
- ▶ the connectives (e.g. $\neg, \wedge, \vee, \rightarrow$, etc.),
- ▶ the quantifiers \forall and \exists ,
- ▶ as well as the round brackets ‘(’ and ‘)’.

Vocabulary (special to Second-Order Logic)

The vocabulary extensions to fit **second-order logic requirements** are:

- ▶ A (potentially infinite) supply of **first-order predicate variables** (e.g. X, Y, Z , etc.), which are necessary to quantify over first-order predicates,
- ▶ a (potentially infinite) supply of **second-order predicate constants** (e.g. $\mathcal{A}, \mathcal{B}, \mathcal{C}$, etc.).

If we wanted to take it even at a higher-order level we could also have:

- ▶ a (potentially infinite) supply of **second-order predicate variables** (e.g. $\mathcal{X}, \mathcal{Y}, \mathcal{Z}$, etc.) to stand in for second-order predicates.

The Semantics of Second-Order Logic

Similar as for the syntax of second-order logic, its semantics can also be defined based on what has been defined for first-order logic before.

For instance, just as a **first-order predicate** denotes a **set of entities**, a **second-order predicate** denotes a **set of a set of entities**.

However, since the formal definitions of valuation functions get increasingly more complex, and the interpretation with regards to natural language examples more abstract, we will not further delve into the issue here.

Summary

Summary

- ▶ **Second-order predicate logic** goes beyond first-order predicate logic by, firstly, introducing **predicate variables**, which allow to quantify over first-order predicates, and secondly, by introducing **second order predicates**, which are to be seen as properties of properties, i.e. predicates over predicates.
- ▶ These changes lead to **adjustments in the formal definitions** of the syntax and semantics of the logical language L .
- ▶ These adjustments enable the translation of a wider array of natural language sentences, although there are still natural language phenomena not captured appropriately.
